Q1. [60 pts] Probabilistic Language Modeling

In lecture, you saw an example of supervised learning where we used Naive Bayes for a binary classification problem: To predict whether an email was ham or spam. To do so, we needed a labeled (i.e., ham or spam) dataset of emails. To avoid this requirement for labeled datasets, let's instead explore the area of unsupervised learning, where we don't need a labeled dataset. In this problem, let's consider the setting of language modeling.

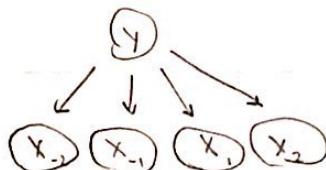

Language modeling is a field of Natural Language Processing (NLP) that tries to model the probability of the next word, given the previous words. Here, instead of predicting a binary label of "yes" or "no," we instead need to predict a multiclass label, where the label is the word (from all possible words of the vocabulary) that is the correct word for the blank that we want to fill in.

One possible way to model this problem is with Naive Bayes. Recall that in Naive Bayes, the features X_1, \dots, X_m are assumed to be pairwise independent when given the label Y . For this problem, let Y be the word we are trying to predict, and our features be X_i for $i = -n, \dots, -1, 1, \dots, n$, where $X_i = i$ th word i places from Y . (For example, X_{-2} would be the word 2 places in front of Y . Again, recall that we assume each feature X_i to be independent of each other, given the word Y . For example, in the sequence Neural networks ____ a lot, $X_{-2} = \text{Neural}$, $X_{-1} = \text{networks}$, $Y = \text{the blank word (our label)}$, $X_1 = \text{a}$, and $X_2 = \text{lot}$.

(a) First, let's examine the problem of language modeling with Naive Bayes.

- (i) [1 pt] Draw the Bayes Net structure for the Naive Bayes formulation of modeling the middle word of a sequence given two preceding words and two succeeding words. You may think of the example sequence listed above:

Neural networks ____ a lot.

- (ii) [1 pt] Write the joint probability $P(X_{-2}, X_{-1}, Y, X_1, X_2)$ in terms of the relevant Conditional Probability Tables (CPTs) that describe the Bayes Net.

$$P(X_{-2}, X_{-1}, Y, X_1, X_2) = P(X_{-2}|Y) P(X_{-1}|Y) P(X_1|Y) P(X_2|Y) P(Y)$$

- (iii) [1 pt] What is the size of the largest CPT involved in calculating the joint probability? Assume a vocabulary size of V , so each variable can take on one of possible V values.

$$V^2$$

- (iv) [1 pt] Write an expression of what label y that Naive Bayes would predict for Y (Hint: Your answer should involve some kind of arg max and CPTs.)

$$\underset{y}{\operatorname{argmax}} P(X_{-2}, X_{-1}, y, X_1, X_2) = \underset{y}{\operatorname{argmax}} P(X_{-2}|y) P(X_{-1}|y) P(X_1|y) P(X_2|y) P(y)$$

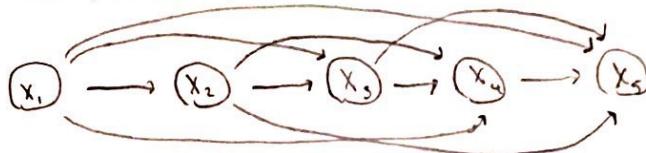

- (v) [3 pts] Describe 2 problems with the Naive Bayes Approach for the general problem of language modeling.
Hint: do you see any problems with the assumptions that this approach makes?

- The vocabulary size is too large so finding the argmax takes too long
- In reality, the independence assumption that all other words are independent given Y doesn't hold

Now, let's change our setting a bit. Instead of trying to fill in a blank given surrounding words, we are now only given the preceding words. Say that we have a sequence of words: X_1, \dots, X_{m-1}, X_m . We know $\{X_i\}_{i=0}^{m-1}$ but we don't know X_m .

- (b) For this part, assume that every word is conditioned on all previous words. We will call this the **Sequence Model**.

- (i) [1 pt] Draw the Bayes Net (of only X_1, X_2, X_3, X_4, X_5) for a 5-word sequence, where we want to predict the fifth word in a sequence X_5 given the previous 4 words X_1, X_2, X_3, X_4 . Again, we are assuming here that each word depends on all previous words.

- (ii) [1 pt] Write an expression for the joint distribution of a general sequence of length m : $P(X_1, \dots, X_m)$.

$$P(X_1, \dots, X_m) = P(X_1) P(X_2 | X_1) P(X_3 | X_1, X_2) P(X_4 | X_1, X_2, X_3) P(X_5 | X_1, X_2, X_3, X_4)$$

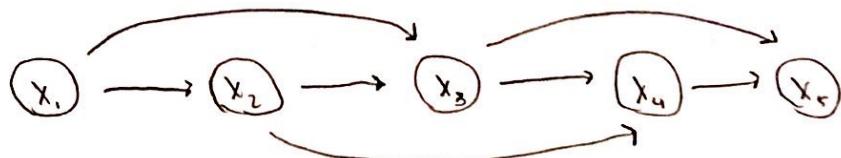

$$P(X_1, \dots, X_m) = P(X_1) \prod_{i=2}^m P(X_i | X_1, \dots, X_{i-1})$$

- (iii) [1 pt] What is the size of the largest CPT involved in calculating the joint probability? Assume a vocabulary size of V , so each variable can take on one of possible V values.

$$V^m$$

- (c) You should have gotten a very large number for the previous part, which shows how infeasible the sequence model is. Instead of the model above, let's now examine another modeling option: N-grams. In N-gram language modeling, we add back some conditional assumptions to bound the size of the CPTs that we consider. We limit the tokens of consideration from "all previous words" to instead using only "the previous $N - 1$ words." This creates the conditional assumption that, given the previous $N - 1$ words, the current word is independent of any word before the previous $N - 1$ words. For example, for $N = 3$, if we are trying to predict the 100th word, then given the previous $N - 1 = 2$ words (98th and 99th words), then the 100th word is independent of words 1, ..., 97 of the sequence.

- (i) [1 pt] Making these additional conditional independence assumptions changes our Bayes Net. Redraw the Bayes Net from part (ci) to represent this new N-gram modeling of our 5-word sequence: X_1, X_2, X_3, X_4, X_5 . Use $N = 3$.

- (ii) [2 pts] Write an expression for the N-gram representation of the joint distribution of a general sequence of length m : $P(X_1, \dots, X_m)$. Please use set notation (for example: For tokens X_i, \dots, X_j , please write something of the form $\{X_k\}_{k=i}^j$). Your answer should express the joint distribution $P(\{X_i\}_{i=1}^m)$, in terms of m and N .

Hint: If you find it helpful, try it for the 5 word graph above first before going to a general m length sequence.

$$P(\{X_i\}_{i=1}^m) = P(X_1) \prod_{i=2}^{m-1} P(X_i | \{X_k\}_{k=1}^{i-1}) \prod_{j=N}^m P(X_j | \{X_k\}_{k=j-N+1}^{j-1})$$

- (iii) [1 pt] What is the size of the largest CPT involved in calculating the joint probability above? Again, assume a vocabulary size of V , and $m > N$.

$$V^N$$

- (iv) [2 pts] Describe one disadvantage of using N-gram over Naive Bayes.

The CPT is larger so it takes longer to compute anything

- (v) [4 pts] Describe an advantage and disadvantage of using N-gram over the Sequence Model above.

Advantage: The CPT is smaller so calculating the anything is faster

Disadvantage: It is less accurate b/c it only assumes dependence on the previous $N-1$ words

- (d) In this question, we see a real-world application of smoothing in the context of language modeling.

Say we have the following training corpus from Ted Geisel:

i am sam . sam i am . i do not like green eggs and ham .

Consider the counts given in the tables below, as calculated from the sentence above.

1-gram	
Token	Count
i	3
am	2
sam	2
.	3
do	1
not	1
like	1
green	1
eggs	1
and	1
ham	1
TOTAL	17

2-gram phrases starting with i		
Token1	Token2	Count
i	am	2
i	do	1
TOTAL		3

2-gram phrases starting with am		
Token1	Token2	Count
am	sam	1
am	.	1
TOTAL		2

- (i) [1 pt] Based on the above dataset and counts, what is the N -gram estimate for $N = 1$, for the sequence of 3 tokens i am ham? In other words, what is $P(i, am, ham)$ for $N = 1$?

$$P(i) \cdot P(am) \cdot P(ham) = \frac{3}{17} \cdot \frac{2}{17} \cdot \frac{1}{17} = \frac{6}{4913}$$

- (ii) [1 pt] Based on the above dataset and counts, what is the N -gram estimate for $N = 2$, for the sequence of 3 tokens i am ham? In other words, what is $P(i, am, ham)$ for $N = 2$?

$$P(i) \cdot P(am|i) \cdot P(ham|am) = \frac{3}{17} \cdot \frac{2}{3} \cdot 0 = 0$$

- (iii) [3 pts] What is the importance of smoothing in the context of language modeling?

Hint: see your answer for the previous subquestion.

It prevents dividing by zero. This prevents us from determining a probability 0 on unobserved data points

- (iv) [5 pts] Perform Laplace k -smoothing on the above problem and re-compute $P(i, am, ham)$ with the smoothed distribution, for $N = 2$. In order to calculate this, complete the pseudocount column for each entry in the probability tables. Note we add a new <unk> entry, which represents any token not in the table.

Hint: the count for the new <unk> row in each table would be 0.

1-gram			
Token	Count	Pseudocount	
i	3	$3+k$	
am	2	$2+k$	
sam	2	$2+k$	
.	3	$3+k$	
do	1	$1+k$	
not	1	$1+k$	
like	1	$1+k$	
green	1	$1+k$	
eggs	1	$1+k$	
and	1	$1+k$	
ham	1	$1+k$	
<unk>	0	k	
TOTAL	17	$17+12k$	

2-gram phrases starting with "i"				2-gram phrases starting with "am"			
Token1	Token2	Count	Pseudocount	Token1	Token2	Count	Pseudocount
i	am	2	$2+k$	am	sam	1	$1+k$
i	do	1	$1+k$	am	.	1	$1+k$
i	<unk>	0	k	am	<unk>	0	k
TOTAL		3	$3+3k$	TOTAL		2	$2+3k$

- (v) [4 pts] What is a potential problem with Laplace smoothing? Propose a solution. (Assume that you have chosen the best k , so finding the best k is not a problem.)

Hint: Consider the effect of smoothing on a small CPT.

On small CPT, the extra observations from smoothing can change the distribution dramatically and make it less accurate given the observed data.
To fix this we can choose k proportional to the # of observations in the CPT

- (vi) [2 pts] Let the likelihood $\mathcal{L}(k) = P(i, am, sam)$, give an expression for the log likelihood $\ln \mathcal{L}(k)$ of this sequence after k -smoothing.

$$L(k) = P(i, am, sam) = P(i) P(am|i) P(sam|am)$$

$$\begin{aligned} \ln L(k) &= \ln P(i) + \ln P(am|i) + \ln P(sam|am) \\ &= \ln \left(\frac{3^{4k}}{17+12k} \right) + \ln \left(\frac{2^{4k}}{5+3k} \right) + \ln \left(\frac{14k}{2+3k} \right) \end{aligned}$$

- (vii) [4 pts] Describe a procedure we could do to find a reasonable value of k . No mathematical computations needed.

Hint: you might want to maximize the log likelihood $\ln \mathcal{L}(k)$ on something.

Maximize the expression wrt k

i.e) compute $\frac{\partial}{\partial k} \ln L(k)$ and find the maximum

Coding Portion: Now we will implement these ideas in code (in a Google Colab Notebook, link posted on piazza) to perform language modeling, and then use the language model to generate some novel text!

- (e) [15 pts] You will implement some of the math you computed earlier to complete the following functions in the provided N-gram class. Note that if you follow our hints, this should not require more than 15 total lines of code for all the functions below.

First, follow the instructions in this PDF to set up your Google Colab Notebook:

<https://drive.google.com/file/d/1SfxH9odurnfYu6N-Z7k3hO4wajIg5he2/view>.

You will need to implement the following functions:

- `count_words`
 1. This function returns a dictionary with the count of each word in `self.text_list`.
 2. HINT: You can do this in one line by using `collections.Counter`.
- `calc_word_probs`
 1. This function converts a dictionary of counts from `count_words` and normalizes the counts into probabilities.
 2. HINT: You can do this in 1-2 lines by using `self.normalize_dict(...)`
- `probs_to_neg_log_probs`
 1. This function converts an inputted dictionary of probabilities `probs_dict` into a dictionary of negative log probabilities.
 2. HINT: Use `np.log`.
- `filter_adj_counter`
 1. This function is a little more complicated. Given a length $N - 1$ tuple of tokens and their associated counts (frequencies), this function searches through all the length N phrases it has stored in `self.adj_counter` (or is passed in via the argument `adj_counter`) and returns a dictionary with only the length N phrases with the same first $N - 1$ words as `word_tuple`, plus their associated counts (frequencies). See the docstring for a concrete example.
 2. HINT1: Use `phrase[:len(word_tuple)]` to get a tuple of the first $N - 1$ words of each N -length phrase in the `adj_counter` to compare with `word_tuple`.
 3. HINT2: We are returning the filtered dictionary which is stored in the variable `subset_word_adj_counter`, so you need to modify this dictionary in some way.
- `p_naive`
 1. This function calculates the non-smoothed empirical probability of a length n phrase occurring given length $n - 1$ tuple of tokens `prev_phrase`. In other words, it calculates $P(\text{current token}|\text{previous } N - 1 \text{ tokens})$. The probability is based on counts, exactly like how we calculated probabilities in the green eggs and ham example earlier in this problem without smoothing.
 2. HINT1: You need to define `prob` because it is being returned.
 3. HINT2: You need to normalize `filtered_adj_counter` which is already defined for you.
- `calc_neg_log_prob_of_sentence`
 1. This function calculates and returns the negative log probability of the entire sequence of tokens `sentence_list` given a probability function `p_func` (which is either the smoothed or the non-smoothed probabilities).
 2. HINT1: `curr_word_prob` is defined for you, and is $P(\text{currToken}|\text{previous } N - 1 \text{ tokens})$.
 3. HINT2: `cum_neg_log_prob` is what the function returns. For each iteration of the for-loop, what must we do to update `cum_neg_log_prob`?
 4. HINT3: Think about how we combine log probabilities for each word.
- `calc_prob_of_sentence`
 1. This function calculates and returns the probability of a sequence of tokens.
 2. HINT1: Use the function you just wrote, `calc_neg_log_prob_of_sentence`.
 3. HINT2: Use `np.exp`.

- (f) [4 pts] After writing the above functions and mounting the corpus on your google drive, you should be able to run the text generation algorithm. This algorithm works by first using the N-gram model to construct CPTs (as we saw earlier in this homework). Then, it uses the CPTs to generate a sequence of words that our model thinks can occur with relatively “high probability.” Our hope is that the “high probability” sequences are sequences of words that make some kind of sense.

Run the text generation algorithm and record (in the spaces below) some of your N-gram model-generated sentences with the following parameters. Please do these in order or else you will be very disappointed by the mediocrity of the text generated. What are the effects of increasing N and k on the quality of the generated text? Modify the N, k variables in the “play with params in code here” section.

1. $N = 1, k = 1$

2. $N = 2, k = 1$

Increasing N makes the sentences more coherent

and the sequence of words is more accurate

3. $N = 2, k = 5$

Increasing k seems to increase the length of the sentences

4. $N = 3, k = 1$

5. $N = 3, k = 5$

- (g) [1 pt] Now, perform language modeling on a dataset/corpus of your choosing. Select a corpus, put it in a text file, and upload it to the google drive folder with all the other .txt files you uploaded earlier. Then redefine `training_corpora_path_list` under the comment “REDEFINE `training_corpora_path_list` here if you wish to use your own corpus” and use the model to perform text generation (as you did above). For good results, select a corpus at least 50,000 words long. If you are not feeling creative, feel free to use the other files in the cs188whw4public folder.

Below, write a sentence that your N-gram model generated on your custom corpus.

but i could say as much to you.

- (h) [0 pts] So far, we have used N-gram to do language modeling and text generation. We can also use N-gram, with some modifications (that staff has already coded for you) to capitalize a sequence of words correctly. This is done using probability maximization; in other words, which options of capitalization look most like things we have seen in the training dataset. The current implementation is slow, but if you were to make a spin-off project, you can look into the Viterbi Algorithm (not in scope for 188 this semester) to speed it up.

Run the capitalization script on the strings provided (you do not need to make any changes for this part). If you wrote your code correctly, you should get capitalizations of the inputted sentences that make sense. In other words, your model is smart enough to know when to capitalize tricky words like “united!”

How to submit code: Copy the full n-gram class into a .py file and submit to Gradescope under “HW 4 Written - Code.”

Q2. [40 pts] Machine Learning

In this question, we will attempt to develop more intuition about how Neural Networks work. In parts A and B, we will discuss gradient descent, and in part C we look at backprop.

- (a) Gradient descent is a procedure which allows you to minimize any loss function. As an example, let's consider a simple function $\text{Loss}(w) = w^2$ and let's assume that we want to minimize this function. Perform gradient descent on this loss function by using the update rule $w \leftarrow w - \alpha \frac{d\text{Loss}}{dw}$, where α is the learning rate.

- (i) [1 pt] What is $\frac{d\text{Loss}}{dw}$? Write your answer in terms of w .

$$\frac{d\text{Loss}}{dw} = 2w$$

- (ii) [1 pt] What is the optimal w that minimizes this loss function? We denote this value of w as w^* .

$$w^* = 0$$

- (iii) [2 pts] Carry out one iteration of gradient descent (i.e., weight update). What is the resulting weight (and corresponding post-update loss) for the scenarios below? Plot the loss function (w^2) by hand and, for each of the two scenarios below, draw the direction in which w is updated (an arrow on the w axis from w_{old} to w_{new}).

1. $\alpha = 0.1, w = 2$

$$w_{\text{new}} = w_{\text{old}} - 0.1(2w_{\text{old}})$$

$$= 1.6$$

$$\text{Loss}(w_{\text{new}}) = 3.2$$

2. $\alpha = 1, w = -2$

$$w_{\text{new}} = -2(-1)(2(-2))$$

$$= 2$$

$$\text{Loss}(w_{\text{new}}) = 4$$

- (iv) [4 pts] Assume w is initialized to some nonzero value. Assume we are still working with $\text{Loss}(w) = w^2$

1. Which value of α allows gradient descent to make w converge to w^* in the least amount of steps?

$$w_{\text{new}} = w_{\text{old}} - \alpha(2w)$$

$$w^* = w(1-2\alpha)$$

$$\alpha = (1 - w^*/w)^{1/2} \quad \text{since } w^* = 0$$

$$\alpha = \frac{1}{2} \quad \text{thus takes 1 step}$$

2. For what range of α does w never converge?

Hint: You may consider for which γ where $w_t = \gamma w_{t-1}$ will never converge.

$$w_{\text{new}} = w - \alpha(2w) = w(1-2\alpha)$$

$$\frac{w_{\text{new}}}{w} \leq 1 - 2\alpha$$

at minimum $\frac{w_{\text{new}}}{w} = 1$ if no convergence so

$$\alpha \leq 0$$

note $\alpha \in [-1, 1]$

- (v) [2 pts] Why must α always be positive when performing gradient descent?

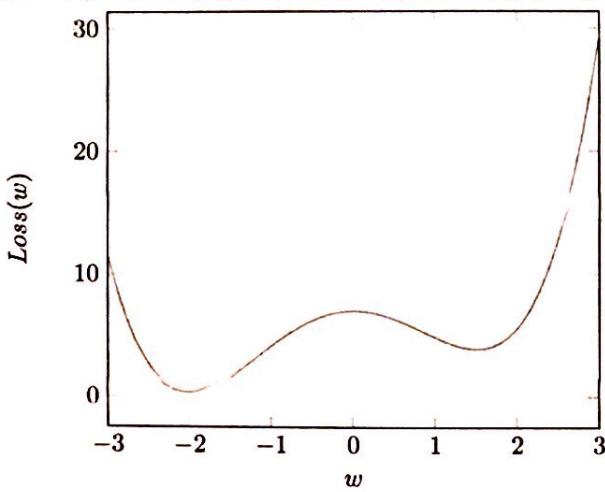

Suppose $\alpha \in [0, 1]$ then

$$w_{\text{new}} = w_{\text{old}} - (-\alpha)(2w)$$

$$= w_{\text{old}} + 2\alpha w$$

so $w_{\text{new}} > w_{\text{old}}$ which always diverges

- (b) It is unlikely that we have a loss function as nice as w^2 . Say we instead want to minimize some more complex loss $\text{Loss}(w) = \frac{w^4}{2} + \frac{w^3}{3} - 3w^2 + 7$, a polynomial with local minima at $w = -2, 1.5$, a global minimum at $w = -2$, a local maximum at $w = 0$, and limits that go to infinity for both $w \rightarrow \infty$ and $w \rightarrow -\infty$.

- (i) [3 pts] Why do Neural Networks use gradient descent for optimization instead of just taking the derivative and setting it equal to 0? You may use the example error function from above to explain your reasoning.

Functions may have many local minima so we want to go in the direction of steepest descent

- (ii) [1 pt] What is the optimal w^* , given the loss above?

$$\frac{\partial \text{loss}}{\partial w} = 2w^3 + w^2 - 6w$$

- (iii) [3 pts] Let α and w take on the values below. For each case, perform some update steps and report whether or not gradient descent converges to the optimum w^* . If not, report whether it converges to some other value, or does not converge to any value.

1. $\alpha = 1, w = 0$

Converges to $w^* = 0$

2. $\alpha = 1, w = -2$

Converges to $w^* = -2$

3. $\alpha = 1, w = 1$

Does not converge

4. $\alpha = 0.1, w = 3$

Converges to $w^* = -2$

5. $\alpha = 0.1, w = 2$

Converges to $w^* = 1.5$

6. $\alpha = 0.1, w = -10$

Does not converge

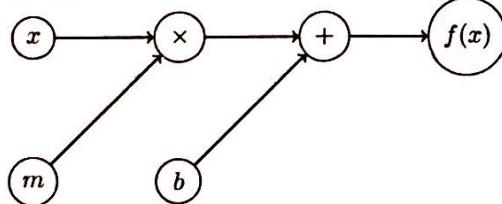

(iv) [3 pts] From the subquestion above, explain the effect of learning rate being (a) too high and (b) too low.

a) A high learning rate may cause over-convergence of weights

b) Low learning rates may cause the model to update too slowly
converge to the wrong optimum

(c) Let's now look at some basic neural networks drawn as computation graphs.

(i) [1 pt] Consider the following computation graph, which represents a 1 layer Neural Network.

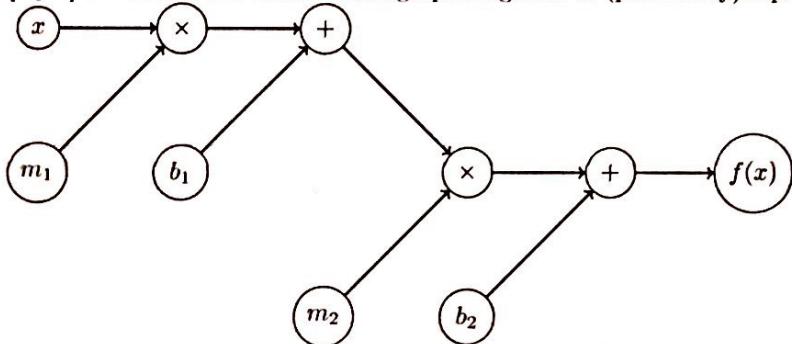

1. Write the equation for the network's output ($y = f(x)$) in terms of m, x, b .

$$f(x) = mx + b$$

2. Describe the types of functions that can be encoded by such a function (given that the variables that it can control are m and b).

linear

- (ii) [2 pts] Let's stack two of the above graphs together to (potentially) represent a 2 layer "Neural Network."

1. Write the equation for $y = f(x)$ in terms of m_1, m_2, b_1, b_2, x .

$$\begin{aligned} f(x) &= m_2(m_1x + b_1) + b_2 \\ &= (m_1m_2)x + (m_2b_1 + b_2) \end{aligned}$$

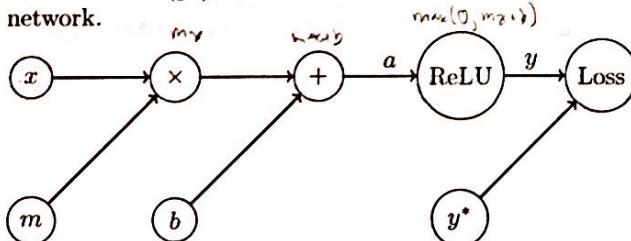

2. Describe the types of functions that can be encoded by such a function (given that the variables that it can control are the 4 learnable parameters m_1, m_2, b_1, b_2). Compare this with the previous neural network's expressive power.

linear the same expressive power

3. Is this actually a 2-layer network? If it is, explain. If not, rewrite it (algebraically) as a 1-layer network with only 2 learnable weights. Why do neural networks need nonlinearities?

No; a linear combination of linear functions is still linear. We need to add nonlinearities to express non-linear functions

- (iii) [4 pts] Now, let's go back to the first NN and add a nonlinearity node. Recall $\text{ReLU}(x) = \max(0, x)$. Also consider a loss function $\text{Loss}(y, y^*)$ which represents the error between our network's output (y) and the true label (y^*) from the dataset. We will perform an abbreviated version of backpropagation on this network.

1. Compute $\frac{\partial \text{Loss}}{\partial a}$ using Chain Rule. Use Mean Squared Error as the loss function, which is defined as $MSE(y, y^*) = (y - y^*)^2$ where y^* = true label and y is the predicted output from the neural network.

$$\begin{aligned} \frac{\partial \text{loss}}{\partial y} &= \frac{\partial}{\partial y} (y - y^*)^2 = 2(y - y^*) & \frac{\partial y}{\partial a} &= \frac{\partial a}{\partial a} = 1 \quad \text{if } a > 0 \\ \frac{\partial \text{loss}}{\partial a} &= \frac{\partial \text{loss}}{\partial y} \cdot \frac{\partial y}{\partial a} = \begin{cases} 2(y - y^*) & \text{if } a > 0 \\ 0 & \text{otherwise} \end{cases} & \frac{\partial a}{\partial b} &= 0 \quad \text{otherwise} \end{aligned}$$

2. Find $\frac{\partial \text{Loss}}{\partial b}$. Note that since we are doing backprop, we can reuse calculations from part 1.

$$\begin{aligned} \frac{\partial a}{\partial b} &= 1 & \frac{\partial \text{loss}}{\partial b} &= \begin{cases} 2(y - y^*) & \text{if } a > 0 \\ 0 & \text{otherwise} \end{cases} \end{aligned}$$

3. Find $\frac{\partial \text{Loss}}{\partial m}$. Note that since we are doing backprop, we can reuse calculations from part 1.

$$\frac{\partial a}{\partial m}, \quad \frac{\partial (mx+b)}{\partial m} = a$$

$$\frac{\partial \text{Loss}}{\partial m}, \quad \begin{cases} 2(y-x)x & \text{if } a > 0 \\ 0 & \text{otherwise} \end{cases}$$

4. What is the gradient descent update rule for updating m ? What is the update rule for b ?

$$m \leftarrow m - \frac{\partial \text{Loss}}{\partial m} \alpha$$

$$b \leftarrow b - \frac{\partial \text{Loss}}{\partial b} \alpha$$

For the next few parts, we analyze the Perceptron algorithm. In the perceptron algorithm, we predict $+1$ if $\vec{w}^T \vec{f}(x) \geq 0$, and predict -1 else, where $\vec{f}(x)$ is a feature vector.

- (d) [3 pts] When implementing the perceptron algorithm with a neural network, the following function might be of use: $\text{sign}(x) = \begin{cases} 1 & \text{if } x \geq 0 \\ -1 & \text{if } x < 0 \end{cases}$. If we added this $\text{sign}(x)$ node to our neural network drawings, what would happen during backpropagation through this node?

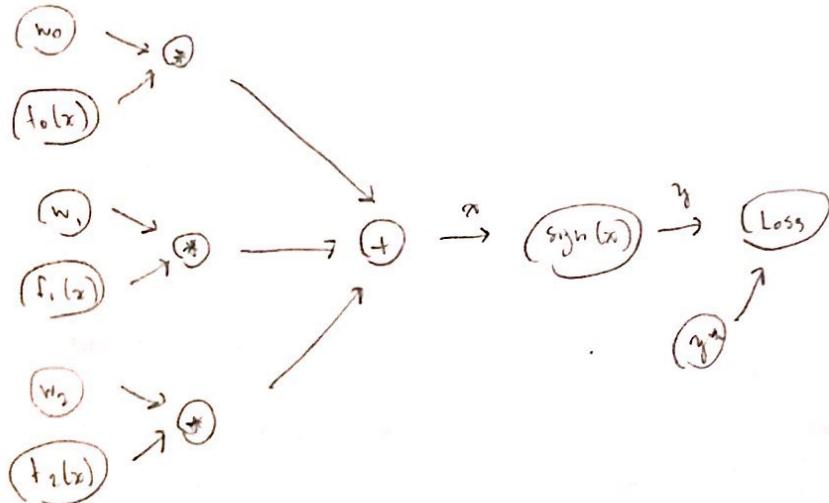

Hint: what does the gradient look like for various x values?

$$\frac{\partial \text{sign}(w)}{\partial x} = 0 \quad \text{so back propagation looks the same}$$

and is always 0

- (e) [2 pts] Draw the binary perceptron prediction function as a “neural-network”-styled computation graph. Assume 3 dimensional weight and feature vectors: that is, $[w_0, w_1, w_2]$ is the weight vector and $[f_0(x), f_1(x), f_2(x)]$ is the feature vector. Recall that in the perceptron algorithm, we take the dot product of the weight vector and the feature vector. In addition to the addition and multiplication nodes, add a loss node at the end, to represent the prediction error which we would like to minimize. Label the edge which represents the perceptron model’s output as y .

Hint: $y = \text{sign}(w_0 * f_0(x) + w_1 * f_1(x) + w_2 * f_2(x))$

- (f) [2 pts] Using Mean Squared Error $(y - y^*)^2$ as the loss function, compute $\frac{\partial \text{Loss}}{\partial w_i}$. Because of the problem you noticed in the previous part with including the sign node, as we are doing chain rule below, use the custom gradient $\frac{\partial \text{sign}(x)}{\partial x} = \left[\frac{\partial \text{sign}(x)}{\partial x} \right]_{\text{custom}} = 1$.

$$\frac{\partial \text{Loss}}{\partial y} = 2(y - y^*)$$

$$\frac{\partial y}{\partial \text{sign}} = 1 \quad \frac{\partial \text{sign}(x)}{\partial x} = 1$$

$$\frac{\partial x}{\partial w_i} = f_i(x)$$

$$\frac{\partial \text{Loss}}{\partial w_i} = 2(y - y^*) f_i(x)$$

(g) In this part, we will derive the gradient update rule for the perceptron using our graph above.

- (i) [1 pt] The loss gradient is defined as $\nabla_w Loss = \begin{bmatrix} \frac{\partial Loss}{\partial w_0} \\ \frac{\partial Loss}{\partial w_1} \\ \frac{\partial Loss}{\partial w_2} \end{bmatrix}$. Using your answer from the previous question, write out the loss gradient.

$$\nabla_w Loss = 2(y - y^*) \begin{bmatrix} w_0 \\ w_1 \\ w_2 \end{bmatrix}$$

- (ii) [4 pts] What is the gradient update rule ($\vec{w} \leftarrow \vec{w} - \alpha \nabla_w Loss$) for the cases below?

Hint: your answers will be in terms of $f(x)$ and α .

1. $y = -1, y^* = 1$

$$\vec{w} \leftarrow \vec{w} - \alpha (2)(-2)\vec{w} = \vec{w}(1+4\alpha)$$

2. $y = 1, y^* = -1$

$$\vec{w} \leftarrow \vec{w} - \alpha (2)(2)\vec{w} = \vec{w}(1-4\alpha)$$

3. $y = y^*$

$$\vec{w} \leftarrow \vec{w}$$

- (iii) [1 pt] For $\alpha = \frac{1}{4}$, compare the update rules you derived for the 3 cases above with the Perceptron update formula in the notes and lecture. Briefly describe your observations.

- 1) $\vec{w}_{new} = 2\vec{w}$ if observation classifies 1 as -1, we double the weight vector meaning classification will be negative
- 2) $\vec{w}_{new} = 0$ if misclassify -1 as 1 our weight vector becomes 0 immediately
- 3) $\vec{w}_{new} = \vec{w}$ proper classification weight vector remains same

Demo portion:

- (h) [0 pts] You used Chain Rule to derive the backpropagation equations for a simple loss function, small network, and low-dimensional problem. As these various aspects of the problem get harder, it quickly becomes impractical to derive every equation by hand. Luckily, there are great libraries available which automate the backpropagation process for the neural networks that you create. Open your Colab notebook and run the NN program that we have provided.

This code revisits the text generation problem from earlier. However, instead of using Naive Bayes or N-grams for modeling, it uses a neural network. Briefly describe the improvements in text generation from using this neural network (the Transformer model) over what you were able to accomplish with N-grams.
